The first two steps are relatively straightforward. The third step involves identifying the specific components of the system that are most likely to cause problems. This can be done by reviewing the system's architecture and identifying potential failure points. Once the components have been identified, the next step is to develop a plan for testing each component. This plan should include a clear definition of the test objectives, a description of the test procedures, and a schedule for completing the tests. Finally, the last step is to execute the tests and analyze the results. This involves running the tests according to the plan and comparing the actual results to the expected results. If there are any discrepancies, the next step is to investigate the causes and take corrective action.
